## A CARBON-13 NUCLEAR MAGNETIC RESONANCE STUDY OF THE PROTONATION OF 5-METHYLRESORCINOL IN SULFURIC ACID SOLUTIONS

(Presented by O. Kirret)

The basicity of some hydroxybenzenes and alkoxybenzenes has already been studied [1–3]. These bases are half-protonated in 75–82% (w/w) aqueous sulfuric acid [4]. Besides a considerable amount of data are available about the protonation sites in hydroxybenzenes and alkoxybenzenes obtained by <sup>1</sup>H and <sup>13</sup>C NMR spectroscopy [5, 6].

### Results and discussion

We wish to report the <sup>13</sup>C NMR observation of protonation of 5-methylresorcinol (5MR) in aqueous sulfuric acid solutions. The <sup>13</sup>C NMR spectrum of 5MR in DMSO is shown in Fig. 1. The assignment of the observed <sup>13</sup>C resonances to carbon atoms in 5MR is based on the equation and increments given by D. F. Ewing [7, 8]. The following chemical shifts (ppm) were calculated by this equation (in brackets the respective chemical shifts measured in DMSO are presented): C-1,3 156.7 (158.1), C-2 99.9 (99.7), C-4,6 109.0 (107.0), C-5 140.5 (139.0), CH<sub>3</sub>- 21.5 (21.2).

The <sup>13</sup>C chemical shifts ( $\delta$ ) of 5MR in water-sulfuric acid mixtures are presented in Table 1. It is evident that the protonation of 5MR causes remarkable changes only in C-1,3 and C-5 chemical shifts (about 35 and 26 ppm to the lower field or frequencies, respectively). The chemical shifts of C-2 and CH<sub>3</sub>- are practically not changed when the sulfuric acid

a — the chemical shift is uncertain because the respective line is broad (more than 15 ppm).

concentration is increased from 0 to 95.7%. The chemical shift of C-4,6 ( $\delta$  (C-4,6)) is not changed in the range of 0—75% H<sub>2</sub>SO<sub>4</sub>. In more concentrated acid solutions  $\delta$  (C-4,6) is split into two lines:  $\delta'$  (C-4,6)  $\approx$  118 ppm and  $\delta''$  (C-4,6)  $\approx$  40 ppm. In 75—80% H<sub>2</sub>SO<sub>4</sub>, the respective components  $\delta'$  and  $\delta''$  are rather broad (10—15 ppm) becoming narrower in more concentrated acid solutions. The appearance of this doublet indicates that in these solutions 5MR becomes C-protonated in position 4,6 (see Fig. 2). As a result, the carbon atoms in positions 1 and 3 become unequal, one being closer to the protonation site than the other, and line C-1,3 is also split into a doublet (Fig. 2). The absence of this doublet in  $\delta$  (C-4,6) at sulfuric acid concentrations lower than 75% allows us to conclude that in these solutions 5MR are presumably protonated on oxygen. A similar conclusion has been drawn about some other phenols [5].

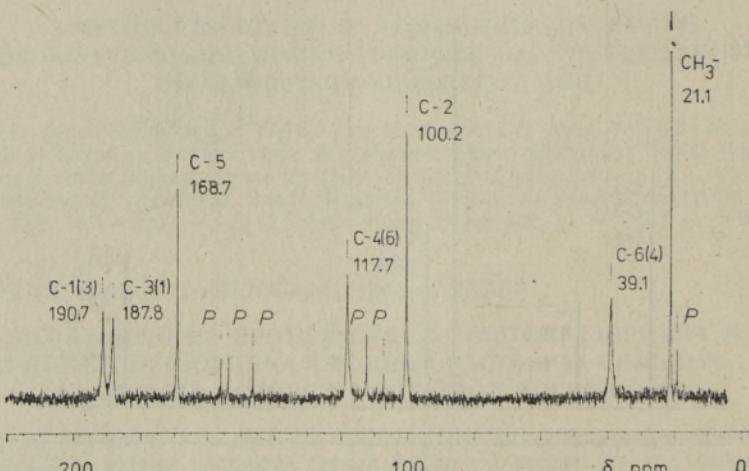

Fig. 2. <sup>13</sup>C NMR spectrum of 5-methylresorcinol (5MR) in 90% H<sub>2</sub>SO<sub>4</sub>. The low intensity signals denoted by P are due to the sulfonation products of 5MR.

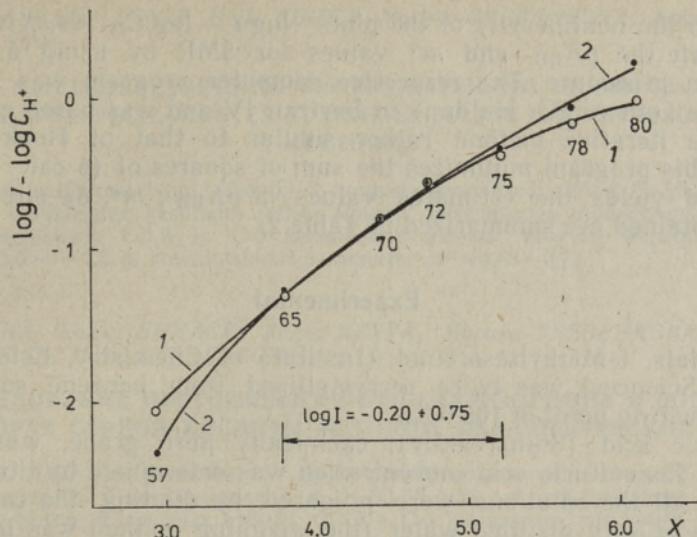

Fig. 3. The plots  $\log I - \log C_{H^+}$  vs. X-function [%]: 1 — C-1,3; 2 — C-5. The numbers at points indicate the sulfuric acid concentrations (% w/w).

The dependences of  $\delta$  (C-1,3) and  $\delta$  (C-5) on the sulfuric acid concentration (see Table 1) may formally be used to estimate the  $pK_{BH^+}$  and  $m^*$  values of 5MR by the Cox-Yates excess acidity method [9]. The indicator ratio  $I = C_{BH^+}/C_B$  values were calculated by

$$I = \frac{\delta_B - \delta}{\delta - \delta_{BH^+}},$$

where  $\delta_B$  and  $\delta_{BH^+}$  are the  $\delta$  values for B and  $BH^+$  forms of the base, respectively. The values of  $I$  were calculated taking C-1, C-3  $\delta_B = 156$  ppm,  $\delta_{BH^+} = 191$  ppm and C-5  $\delta_B = 143$  ppm,  $\delta_{BH^+} = 168.9$  ppm. The plots  $\log I - \log C_{H^+}$  vs. X-function [%] show (see Fig. 3) the carbon atoms C-1, C-3 and C-5 to exhibit practically the same dependence  $\log I - \log C_{H^+}$  vs. X. But except the region 65–75%  $H_2SO_4$  ( $-0.2 < \log I < 0.75$ ), these plots are not linear as expected. Therefore, the  $pK_{BH^+}$  and  $m^*$  values of 5MR were calculated [9] using the  $\log I$  values in the range  $-0.2 < \log I < 0.75$  only. This procedure yields for 5-methylresorcinol  $pK_{BH^+} = -3.64$  and  $m^* = 0.63$ .

Table 2

The  $pK_{BH^+}$  and  $m^*$  values for 5-methylresorcinol

| Method and carbon atom         | $pK_{BH^+}$ | $m^*$ | $\delta_B$ , ppm | $\delta_{BH^+}$ , ppm |
|--------------------------------|-------------|-------|------------------|-----------------------|
| Classical Cox-Yates method [9] |             |       |                  |                       |
| C-1, C-3                       | -3.65       | 0.63  | 156.0            | 191.0                 |
| C-5                            | -3.63       | 0.63  | 143.0            | 168.9                 |
| Nonlinear regression procedure |             |       |                  |                       |
| C-1, C-3                       | -4.25       | 0.78  | 155.7            | 189.7                 |
| C-5                            | -4.17       | 0.76  | 142.3            | 168.5                 |

Due to the nonlinearity of the plots  $\log I - \log C_{\text{H}^+}$  vs.  $X$  we decided to calculate the  $pK_{\text{BH}^+}$  and  $m^*$  values for 5MR by using a nonlinear regression procedure. The respective computer program was written by one of the authors (Ü. Haldna) in Fortran IV and was based on the non-derivative iterative method rather similar to that of Hook and Jeeves [10]. This program minimizes the sum of squares of ( $\delta$  calc. —  $\delta$  experim.) and yields the estimated values of  $pK_{\text{BH}^+}$ ,  $m^*$ ,  $\delta_B$  and  $\delta_{\text{BH}^+}$ . The results obtained are summarized in Table 2.

## Experimental

**Materials.** 5-Methylresorcinol (Institute of Chemistry, Estonian Academy of Sciences) was twice recrystallized from benzene solution and had the melting point of 106.5°C.

Sulfuric acid (Sojureaktiv), chemically pure grade, was used as supplied. The sulfuric acid concentration was determined by titration with  $\text{Na}_2\text{CO}_3$ . All the solutions were prepared by diluting the concentrated sulfuric acid with distilled water (the weighing method was used).

The solutions of 5-methylresorcinol were prepared by dissolving this compound in aqueous sulfuric acid. The concentrations of 5-methylresorcinol were in the 0.5—2.5% (w/w) range.

**Chemical shift measurements.**  $^{13}\text{C}$  magnetic resonance spectra were run on a Bruker AC-200 spectrometer operating in the pulsed Fourier transform mode. In order to obtain the NMR spectrum of 5-methylresorcinol from its 0.5—2.5% (w/w) solution in aqueous sulfuric acid, about 30000 pulses were used (the total time for obtaining a spectrum was 12.5 hours). 5-Methylresorcinol with the natural abundance of  $^{13}\text{C}$  was used. The chemical shifts, represented in Table 1, were measured relative to the shift of the  $\text{CH}_3$ -group carbon atom taking  $\delta(\text{CH}_3) = 21.2$  ppm (i. e. its value in DMSO).
