CAMBRIAN-LOWER ORDOVICIAN BOUNDARY BEDS IN NORTHERN POLAND

The Ordovician deposits in the Polish part of the peri-Baltic syneclyse are known from numerous borings (Bednarczyk, 1968, 1979; Modliński, 1973). They are represented by lithofacies types that are characteristic of the facies zones distinguished in Baltoscandia by Männil (Мянниль, 1966) and later specified by Jaanusson (1976). The first of them — the Scanian confacies belt — extends to the Łeba area (the westernmost part of the peri-Baltic syneclyse), and the second one — the central Baltoscandian confacies belt — reaches the eastern part of the peri-Baltic syneclyse, including the northeastern part of Poland (Fig. 1).

In the Łeba area the Lower Ordovician begins with claystones intercalated with beds of glauconitic grey limestones with conodonts of the *Paltodus deltifer* Zone (Bednarczyk, 1979) that overlies concordantly the Upper Cambrian black claystones of the Acerocare Zone (Figs 1 and 2, see the Białogóra 1 section) or starts with variable in thickness glauconites layers grading upward into claystones of the *Tetragraptus phyllograptoides* Zone? (Fig. 2, the Białogóra 2 and Zarnowiec-IG1 sections) or into the similar sediments of the *Didymograptus balticus* Zone (Fig. 2, the Dębki 2 and Dębki 3 and Piaśnica 2 sections). In this area the Lower Ordovician deposits cover various members of the Upper Cambrian claystones intercalated of limestone with trilobite of the *Agnostus pisiformis* or the *Peltura scarabeoides* Zone (Fig. 2).

In contrast to the Lower Ordovician of the Łeba area, the coeval deposits in the eastern part of the peri-Baltic syneclyse consist of sandy-carbonate rocks. In some sections the Lower Tremadocian starts with sandy-conglomeratic deposits with *Obolus apollinis*, and in other profiles the Lower Arenigian begins with glauconites of the *Prioniodus elegans* Zone or even more frequently with the glauconites passing upwards

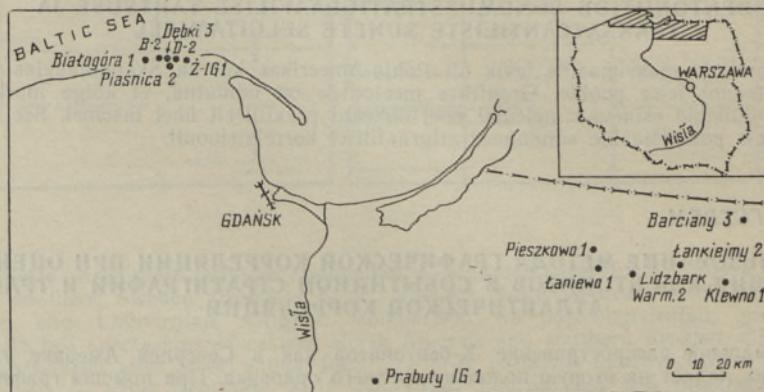

Fig. 1. Location of boreholes (oblique lines — investigated area).

into the glauconitic limestones with conodonts of the *Oepikodus evae* Zone (Fig. 3). The Lower Ordovician of this territory overlies in places the Upper Cambrian sandy-carbonate deposits with trilobites of the *Agnostus pisiformis* Zone or more often the Middle Cambrian sandstones (Bednarczyk, 1984; Lendzion, 1983).

On the basis of the above-mentioned data one can distinguish several sedimentary episodes in the section embracing the Upper Cambrian up to the Lower Ordovician in the northeastern part of Poland. These episodes appear to be connected with the transgressive-regressive events distinguished by Miller (1984) and Erdtmann (1986). Similar phenomena were observed in the Upper Cambrian to the Lower Ordovician sections in the rest of the territory of Poland (Fig. 4) (Biernat, Bednarczyk, in prep.).

These are as follows: 1) uppermost Cambrian-Lowermost Tremadocian regression coinciding with Acerocare Regressive Event (ARE) of Erdtmann (1986) or Lange Ranch Eustatic Event (LREE) of Miller (1984); 2) Upper Tremadocian transgressive phase preceded by a regression connected with Peltocare Regressive Event (PRE) of Erdtmann (1986) or Black Mountain Regressive Event of Miller (1984). This phase is characterized by muddy-silty-glaucous or marly-glaucous sediments in the Polish part of the East-European craton or by siliceous rocks in the Holy Cross Mts (Bednarczyk, 1971). The sediments contain rich and diversified faunas (inarticulata, graptolites, trilobites and conodonts); 3) Tremadocian-Arenigian transgressive-regressive phase with carbonate and/or sandy-carbonate (with glauconite) sedimentation. There are many stratigraphic gaps, usually local, sometimes very short and in some places a certain sedimentary stagnation has been stated and probably connected with a deep erosion. This phase is connected with the Ceratopyge Regressive Event (CRE) of Erdtmann (1986); 4) regressive phase at the end of the Billingen and before the sedimentation of the Volkovian deposits may be connected with the Valhall Regressive Event (VRE) of Erdtmann (1986) (Fig. 4).

The transgressive-regressive phases in the Lower Ordovician of Poland mentioned above are in the author's opinion a reflection of eustatic changes of sea level and considerable climatic alterations caused by subsequent intensification of glacial periods.

In some cases the sedimentation of the Upper Cambrian to the Lower Ordovician deposits was broken up by the intermittent period of the intensity of uplifting block movements in the substratum but these factors were only of secondary importance as compared to the above-mentioned agent.

KAMBRIUMI JA ALAMORDOVIITSIUMI PIIRIKIHID PÖHJA-POOLAS

Piirihiitide kivimilise ja faunistilise koostise muutumise alusel on eristatud läbilõike tekkel neli sündmust: 1) regressioon kambriumi lõpul ja Tremadoci algul; 2) transgresioon ja regressioon Hilis-Tremadocis; 3) transgressioon ja regressioon Tremadoci ja Arenigi vahetusel ja 4) regressioon Billingeni aja lõpul.

ПОГРАНИЧНЫЕ СЛОИ КЕМБРИЯ И ОРДОВИЦА В СЕВЕРНОЙ ПОЛЬШЕ

На основе изменений литологического и фаунистического составов пограничных отложений в разрезе выделяются следующие события: 1. регрессия в конце кембрия и начале тремадока; 2. трансгрессия-регрессия в позднем тремадоке; 3. трансгрессия-регрессия при переходе от тремадока в арениг; 4. регрессия в конце биллингена.
